Attention:

The Technical Manager
Eskom Holdings

SUBJECT: REVIEW OF ESKOM REPORT: Electric and Magnetic Fields from Overhead Power Lines – A Summary of Technical and Biological Aspects

Optimum Engineering Consultants hereby confirm that it reviewed a report compiled by Dr P.H Pretorius of Empetus Close Corporation which was compiled for Eskom Holdings in 2006 and concluded that the report is still valid to facilitate environmental impact assessments at Eskom.

In reaching this conclusion Optimum Engineering

- Established validity of original findings based on acceptable published research
- Established latest findings based on acceptable published research
- Compared original findings against latest findings and established relevancy and validity
- Reviewed literature around subject matter

As part of this review process, Optimum compiled report attached as part of its submission and recommendation

Please do not hesitate to contact us for more information

Kind Regards

EXECUTIVE SUMMARY

Optimum Engineering was appointed to review an Eskom report : Electric and Magnetic Fields from Overhead Power Lines – A Summary of Technical and Biological Aspects which was compiled by Empetus Close Corporation in 2016 . The purpose of the review was to establish the validity of the report's findings 11 years after it was compiled and to certify if it can still be used in its current form

The approach followed included

- Literature review around subject matter
- Establishing validity of original findings based on acceptable published research
- Establish latest findings based on acceptable published research
- Compare original findings against latest findings and compare relevancy and validity
- Make recommendations

Background

Research into EMF and health is a complex area involving many disciplines, from biology, physics and chemistry to medicine, biophysics and epidemiology. EMF at levels well above the recognized international exposure guidelines can cause both synaptic effects perceived as magneto-phosphenes in the sensitive retinal tissue (magnetic fields) and micro-shocks (electric fields). The exposure guidelines are in place to protect against these biological effects. No single study considered in isolation will provide a meaningful answer to the question of whether or not EMF can cause or contribute to adverse health effects. In order to make an informed conclusion from all of the research, it is necessary to consider the science in its totality. Over the years, governments and regulatory agencies around the world have commissioned many independent scientific review panels to provide such overall assessments.

1 ORIGINATOR OF REPORT

The report to be analysed was prepared by Doctor P H Pretorius of Empetus Close Corporation on the 18th of August 2006. It has been named as report number EMP / D / 06 / 005 / R01 for project coded EMP / D / 06 / 005 and it is the final report.

2 SCOPE OF THE REPORT

The report outlines existence of electrical and magnetic fields (EMFs) around electrical power infrastructure and gadgets that consume electricity. It also outlines methods of measurement and analysis of these EMFs as well as the impact which they have on human health, plants, animals and other surrounding infrastructure.

3 PURPOSE OF REPORT

The report helps private practitioners, environmentalists and local authorities in planning or citing routes for high voltage infrastructure as well as carrying out developments around high voltage infrastructure. It is more suitable for environmental impact assessments. It lists technical and biological aspects accompanied with existence of high voltage infrastructure in a society or area of interest. The following matters have been highlighted in the report:

- Electric fields are due to system voltage and tend to be stable. They can be shielded and their effect decreases with increased distance from the source.
- Magnetic fields result from the flow of current towards the load and tend to fluctuate tremendously. Reducing the effect of magnetic fields is more challenging and calls for

special engineering techniques. Magnetic fields can penetrate air, human bodies, water, stones, and plants.

4 BASIS OF REPORT ANALYSIS

The analysis of the report strictly considered the following parameters

- i. To establish whether the information contained in the report which gathered information from various research bodies, case studies and laboratories, as compiled by Dr. PH Pretorius is still applicable on the new market.
- ii. To compare the contents of the report against outlines from newly updated standards that are exploited in science and engineering as guidelines during environmental impact assessments related to EMFs. This applies to biological and technical matters that are considered in building new power plants OR developing land near high voltage plants.
- iii. To compare methods of measurements and analysis of signals emanating from EMFs & their effects against those in standards & scientific journals.
- iv. To compare general safety recommendations and precautions to which caution has to be exercised when planning to site new high voltage power plants OR new developments near high voltage plants.

5 PEFERENCE TO STANDARD AND RESEARCH ORGANIZATIONS

Updated reviews on the topic of EMFs have been assessed for the purpose of comparison against Dr. P H Pretorius' report. The currently reviewed pieces of information were picked from journals and standard books prepared by the following organizations:

- SANS/SABS
- ITU-T
- IEC
- IEEE
- Australian Radiation Protection and Nuclear Safety Agency(ARPANSA)
- New Zealand Electrical Code Of practice
- Energy Networks Association
- Environmental Protection Agency (EPA)

- National Radiological Protection Board (NRPB)
- National Academy of Science (NAS)
- National Institute for Environmental Health Sciences (NIEHS)
- International Agency for Research on Cancer (IARC)
- International Commission for Non- Ionizing Radiation Protection (ICNIRP)

Observations are as follows:

- No significant content differences could be picked against the report compiled by Doctor P H Pretorius.
- Reference has also been made to ITU-T K.90, SANS62110 and IEC62110 (Year 2009) and contents of the report under analysis comply with outlines in these standards.

6 SUMMARY OF OUTLINES

Common facts picked from standards, updated journals and Dr. P Pretorius' report can be presented as follows:

NIEHS

Electrical objects produce two types of fields – electric fields and magnetic fields. The term “field” is used to describe the way an object influences its surrounding area. A temperature field, for example, surrounds a warm object, such as a space heater.

Electric and magnetic fields (EMF) surround any object that is generating, transmitting or using electricity, including appliances, wiring, office equipment, distribution lines and transmission lines. EMFs are invisible and they cannot be felt or heard.

- Electric fields are produced by the voltages applied to electrical objects, and
- Magnetic fields are produced by the flow of current through these objects.

Just like a temperature field, electric and magnetic field levels decrease quickly with distance. If you measure the temperature right next to a pot of boiling water, it is high. But, move one or two feet away from the pot and the temperature decreases.

It is the same with EMF. Electric field levels are also affected by nearby objects, such as buildings and trees, which block the fields. A great amount of research has been done on EMF and health, most of which has focused on magnetic fields. Based on this research, no health or scientific agency has concluded that these fields are the cause of any disease. This brochure

describes EMF and the research that has been conducted to date. Since electricity plays an essential role in modern society, we are surrounded by magnetic fields in our homes, offices and schools. As illustrated below, these magnetic fields are higher close to the source and decrease quickly with distance. Magnetic fields are measured with an instrument called a gaussmeter in units called

milligauss (mG). Compared to appliances, the magnetic fields from power lines drop off more slowly with distance. Transmission lines, however, are generally not close enough to locations where we spend a substantial amount of time to contribute significantly to our magnetic field exposure.

The conclusions of scientific panels, overall, have been consistent. World Health Organization (WHO) whose mandate is to provide leadership on global health matters, released an extensive review in June 2007, after more than 10 years of intensive study and consideration. The conclusions of WHO's report and reports by other agencies can be summarized as follows:

- Overall, the scientific evidence does not demonstrate that exposure to EMF causes any disease.
- A weak association exists in epidemiology studies between childhood leukemia and average exposure to higher levels of magnetic fields to which few persons are exposed. These epidemiology studies have recognized limitations and research will continue to clarify this finding.
- Studies in animals have not supported a conclusion that magnetic fields cause leukemia or any other cancer.
- Studies conducted in the laboratory on cells and tissues have not found any mechanism to explain how magnetic fields could cause disease in humans.
- Because the epidemiology studies have limitations and the experimental studies provide little or no support for an association with cancer, WHO did not conclude that magnetic fields cause childhood leukemia, or any other disease.

Considering all of the research together, the reviewers for the WHO report and other agencies have not concluded that magnetic fields cause any long-term, adverse health effects. Additional research on focused topics was recommended.

IARC

While IARC examined the evidence regarding cancer in 2002, this Task Group reviewed evidence for a number of health effects, and updated the evidence regarding cancer. The conclusions and recommendations of the Task Group are presented in a WHO Environmental Health Criteria (EHC) monograph (WHO, 2007).

REF: IARC Working Group on the Evaluation of Carcinogenic Risks to Humans. Non-ionizing radiation, Part 1: Static and extremely low-frequency (ELF) electric and magnetic fields. Lyon, IARC, 2002 (Monographs on the Evaluation of Carcinogenic Risks to Humans, 80).

WHO

In October 2005, WHO convened a Task Group of scientific experts to assess any risks to health that might exist from exposure to ELF electric and magnetic fields in the frequency range >0 to 100,000 Hz (100 kHz). While IARC examined the evidence regarding cancer in 2002, this Task Group reviewed evidence for a number of health effects, and updated the evidence regarding cancer. The conclusions and recommendations of the Task Group are presented in a WHO Environmental Health Criteria (EHC) monograph (WHO, 2007).

Following a standard health risk assessment process, the Task Group concluded that there are no substantive health issues related to ELF electric fields at levels generally encountered by members of the public. Thus the remainder of this fact sheet addresses predominantly the effects of exposure to ELF magnetic fields. There are established biological effects from acute exposure at high levels (well above 100 μ T) that are explained by recognized biophysical mechanisms. External ELF magnetic fields induce electric fields and currents in the body which, at very high field strengths, cause nerve and muscle stimulation and changes in nerve cell excitability in the central nervous system.

Non-ionizing radiation, Part 1: Static and extremely low-frequency (ELF) electric and magnetic fields. Lyon, IARC, 2002 (Monographs on the Evaluation of Carcinogenic Risks to Humans, 80).

ICNIRP

REF1: International Commission on Non-Ionizing Radiation Protection. Exposure to static and low frequency electromagnetic fields, biological effects and health consequences (0-100 kHz). Bernhardt JH et al., eds. Oberschleissheim, International Commission on Non-ionizing Radiation Protection, 2003 (ICNIRP 13/2003).

REF2: International Commission on Non-Ionizing Radiation Protection (1998). Guidelines for limiting exposure to time varying electric, magnetic and electromagnetic fields (up to 300 GHz). Health Physics 74(4), 494-522.

NRPB

On March 31 2004 the NRPB announced that its advice was now that the UK should adopt the ICNIRP exposure guidelines. The guidelines are expressed in terms of “basic restrictions” and “investigation levels”.

- The basic restriction relates directly to the effect on the body of exposure to fields.

- At power frequencies, the principal basic restriction is that the induced current in the body should not exceed 10 mA m⁻² in certain specified parts of the body.

It is not possible to measure the induced current in the body directly. To aid in assessing whether the basic restriction is exceeded or not, the NRPB gives investigation levels.

- At power frequencies, for electric fields, the investigation level for human exposure is 12 kV m⁻¹,
- for magnetic fields it is 1,600 micro Teslas (μT).
- If the field is less than the investigation level, the basic restriction will not be exceeded, and no further investigation is needed.
- If the field exceeds the investigation level, it does not necessarily follow that the basic restriction is exceeded, but further investigation is necessary.

At power frequency:

- Basic restriction: induced current density in the central nervous system 10 mA m⁻²
- Investigation level for magnetic fields: 1600 μT
- Investigation level for electric fields: 12 kV m⁻¹

In setting their Guidance, the NRPB looks at all the evidence for all possible suggested effects of EMFs on people. The actual numbers are chosen to prevent effects of magnetic fields on the body through induced currents and indirect effects such as microshocks. The NRPB looks at the scientific evidence that EMFs may cause cancer, but does not consider this evidence strong enough to justify setting guidelines.

In 2001 the NRPB's Advisory Group on Non-Ionising Radiation (AGNIR) produced a major report on the evidence that EMFs may be linked to cancer. In response, the NRPB stated in part:

"Guidelines for limiting exposure to electromagnetic fields are presently based on preventing established health effects, which for ELF EMFs are those related to induced currents in the tissues of the central nervous system. Epidemiological studies are also taken into account. The Board considers that the AGNIR report provides no additional scientific evidence to require a change in exposure guidelines"

Although the various reports of the NRPB Advisory Group concentrate on cancer and neurodegenerative disease, the studies which the Board take into account when setting exposure guidelines include other suggested health effects. For example, the NRPB exposure guidelines state:

"Epidemiological studies of general health and birth outcome in populations exposed to electromagnetic fields have been reviewed in a Board report. These studies do not appear to show long-term health effects from the levels of electromagnetic fields to which people are normally exposed."

However, although NRPB concludes these studies do not justify quantitative exposure limits, it does suggest they may justify considering precautionary approaches.

The summary Statement says:

“An association between prolonged exposure to intense power frequency magnetic fields and a small raised risk of childhood leukaemia has, however, been found, the scientific reasons for which are presently uncertain. In light of these findings and the requirement for additional research, the need for further precautionary measures should be considered by government.”

The main body of the document states:

“There remain concerns about the possible effects of exposure of children to power frequency magnetic fields. The view of NRPB is that it is important to consider the possible need for further precautionary measures in respect of exposure to children to power frequency magnetic fields.”

“The government should consider the need for further precautionary measures in respect of exposure of people to EMFs. In doing so, it should note that the overall evidence for adverse effects of EMFs on health at levels of exposure normally experienced by the general public is weak. The least weak evidence is for the exposure of children to power frequency magnetic fields and childhood leukaemia.

The NRPB’s role is to provide advice to Government. Its advice does not have direct force on either industry or the public.

In August 2004, in response to the NRPB’s recommendation, the Parliamentary Under Secretary for Public Health (Melanie Johnson) wrote to the Chairman of the NRPB welcoming the new advice. The letter included a 10 point annex describing the way Government intends to implement the NRPB advice. It points to the need for inter-departmental working and introduces the initial plans for a wider stakeholder process in order to consider the possible need for further precautionary measures in respect of extremely low frequency (ELF) electromagnetic fields (EMF).

The key statement about implementation is:

“... the Government expects the NRPB guidelines to be implemented in line with the terms of the EU Recommendation, that is, taking account of the risks and benefits of action. Preliminary discussions have already taken place to identify what reasonable actions might be taken.”

On precautionary measures, it says:

“The Government will be exploring further the practical applications of precautionary measures within a stakeholder engagement process. This will be the subject of wide consultation and will explore any risks and benefits arising in the same manner as a Regulatory Impact Assessment.”

EPA

Electromagnetic fields (EMF) are a combination of electric and magnetic fields of energy that surround any electrical device that is plugged in and turned on.

- Scientific experiments have not clearly shown whether or not exposure to EMF increases cancer risk. Scientists continue to conduct research on the issue.
- The strength of electromagnetic fields fades with distance from the source. Limiting the amount of time spent around a source and increasing the distance from a source reduces exposure.

Electromagnetic fields (EMF) are a combination of electric and magnetic fields of energy that surround any electrical device that is plugged in and turned on. Electromagnetic radiation consists of waves of electric and magnetic energy moving together through space. Electric fields are produced by electric charges and magnetic fields are produced by the flow of current through wires or electrical devices.

EMFs are found near power lines and other electronic devices such as smart meters. Electric and magnetic fields become weaker as you move further away from them. The fields from power lines and electrical devices have a much lower frequency than other types of EMF, such as microwaves or radio waves. EMF from power lines is considered to be extremely low frequency. Scientific studies have not clearly shown whether exposure to EMF increases cancer risk. Scientists continue to conduct research on the issue.

In the United States, there are no federal standards limiting electromagnetic fields from power lines and other sources to people at work or home. Some states set standards for the width of right-of-ways under high-voltage transmission lines because of potential for electric shock.

There is no clear scientific evidence that electromagnetic fields affect health. However, if you are concerned about possible health risks from electric and magnetic fields you can reduce your exposure by:

- Increasing the distance between yourself and the source - The greater the distance between you and the source of EMF, the less your exposure.
- Limiting the time spent around the source - The less time you spend near EMF, the lower your exposure.

REF: <https://www3.epa.gov/radtown/electric-magnetic-fields.html>(Last updated on 8/7/2017)

National Science Academy

Public concern regarding possible health risks from residential exposures to low-strength, low-frequency electric and magnetic fields produced by power lines and the use of electric appliances has generated considerable debate among scientists and public officials. In 1991, Congress asked that the National Academy of Sciences (NAS) review the research literature on the effects from exposure to these fields and determine whether the scientific basis was sufficient

to assess health risks from such exposures. In response to the legislation directing the U.S. Department of Energy to enter into an agreement with the NAS, the National Research Council convened the Committee on the Possible Effects of Electromagnetic Fields on Biologic Systems. The committee was asked "to review and evaluate the existing scientific information on the possible effects of exposure to electric and magnetic fields on the incidence of cancer, on reproduction and developmental abnormalities, and on neurobiologic response as reflected in learning and behaviour." The committee was asked to focus on exposure modalities found in residential settings. In addition, the committee was asked to identify future research needs and to carry out a risk assessment insofar as the research data justified this procedure. Risk assessment is a well-established procedure used to identify health hazards and to recommend limits on exposure to dangerous agents. Based on a comprehensive evaluation of published studies relating to the effects of power-frequency electric and magnetic fields on cells, tissues, and organisms (including humans), the conclusion of the committee is that the current body of evidence does not show that exposure to these fields presents a human-health hazard. Specifically, no conclusive and consistent evidence shows that exposures to residential electric and magnetic fields produce cancer, adverse neurobehavioral effects, or reproductive and developmental effects.

The committee reviewed residential exposure levels to electric and magnetic fields, evaluated the available epidemiologic studies, and examined laboratory investigations that used cells, isolated tissues, and animals. At exposure levels well above those normally encountered in residences, electric and magnetic fields can produce biologic effects (promotion of bone healing is an example), but these effects do not provide a consistent picture of a relationship between the biologic effects of these fields and health hazards. An association between residential wiring configurations and childhood leukemia persists in multiple studies, although the causative factor responsible for that statistical association has not been identified. No evidence links contemporary measurements of magnetic-field levels to childhood leukemia.

Epidemiologic studies are aimed at establishing whether an association can be documented between exposure to a putative disease-causing agent and disease occurrence in humans. The driving force for continuing the study of the biologic effects of electric and magnetic fields has been the persistent epidemiologic reports of an association between a hypothetical estimate of electric-and magnetic-field exposure called the wire-code classification and the incidence of childhood leukemia. These studies found the highest wire-code category is associated with a rate of childhood leukemia (a rare disease) that is about 1.5 times the expected rate.

A particular methodologic detail in these studies must be appreciated to understand the results. Measuring residential fields for a large number of homes over historical periods of interest is logistically difficult, time consuming, and expensive, so epidemiologists have classified homes according to the wire code (unrelated to building codes) to estimate past exposures. The wire-

code classification concerns only outdoor factors related to the distribution of electric power to residences, such as the distance of a home from a power line and the size of the wires close to the home. This method was originally designed to categorize homes according to the magnitude of the magnetic field expected to be inside the home. Magnetic fields from external wiring, however, often constitute only a fraction of the field inside the home. Various investigators have used from two (high and low) to five categories of wire-code classifications. The following conclusions were reached on the basis of an examination of the epidemiologic findings:

- Living in homes classified as being in the high wire-code category is associated with about a 1.5-fold excess of childhood leukemia, a rare disease.
- Magnetic fields measured in the home after diagnosis of disease in a resident have not been found to be associated with an excess incidence of childhood leukemia or other cancers.

The link between wire-code rating and childhood leukemia is statistically significant (unlikely to have arisen from chance) and is robust in the sense that eliminating any single study from the group does not alter the conclusion that the association exists. How is acceptance of the link between wire-code rating and leukemia consistent with the overall conclusion that residential electric and magnetic fields have not been shown to be hazardous? One reason is that wire-code ratings correlate with many factors—such as age of home, housing density, and neighbourhood traffic density—but the wire-code ratings exhibit a rather weak association with measured residential magnetic fields. More important, no association between the incidence of childhood leukemia and magnetic-field exposure has been found in epidemiologic studies that estimated exposure by measuring present-day average magnetic fields.

- Studies have not identified the factors that explain the association between wire codes and childhood leukemia.

Because few risk factors for childhood leukemia are known, formulating hypotheses for a link between wire codes and disease is very difficult. Although various factors are known to correlate with wire-code ratings, none stands out as a likely causative factor. It would be desirable for future research to identify the source of the association between wire codes and childhood leukemia, even if the source has nothing to do with magnetic fields.

- In the aggregate, epidemiologic evidence does not support possible associations of magnetic fields with adult cancers, pregnancy outcome, neurobehavioral disorders, and childhood cancers other than leukemia.

The preceding discussion has focused on the possible link between magnetic-field exposure and childhood leukemia because the epidemiologic evidence is strongest in this instance; nevertheless, many epidemiologists regard such a small increment in incidence as inherently unreliable. Although some studies have presented evidence of an association between magnetic-

field exposure and various other types of cancer, neurobehavioral disorders, and adverse effects on reproductive function, the results have been inconsistent and contradictory and do not constitute reliable evidence of an association.

The purpose of exposure assessment is to determine the magnitudes of electric and magnetic fields to which members of the population are exposed.

The electromagnetic environment typically consists of two components, an electric field and a magnetic field. In general, for time-varying fields, these two fields are coupled, but in the limit of unchanging fields, they become independent. For frequencies encountered in electric-power transmission and distribution, these two fields can be considered independent to an excellent approximation. For extremely-low-frequency fields, including those from power lines and home appliances and wiring, the electric component is easily attenuated by metal elements in residential construction and even by trees, animals, and people. The magnetic field, which is not easily attenuated, is generally assumed to be the source of any possible health hazard. When animal bodies are placed in a time-varying magnetic field (as opposed to remaining stationary in the earth's static magnetic field), currents are induced to flow through tissues. These currents add to those that are generated internally by the function of nerve and muscle, most notably currents detected in the clinically useful electroencephalogram and the electrocardiogram. The currents produced by nerve and muscle action within the body have no known physiologic function themselves but rather are merely a consequence of the fact that excitable tissue (such as nerve and muscle) generate electric currents during their normal operation.

General conclusions from the review of the literature involving studies of exposure assessment and the physical interactions of electric and magnetic fields with biologic systems are the following:

- Exposure of humans and animals to external 60-hertz (Hz) electric and magnetic fields induces currents internally.

The density of these currents is non-uniform throughout the body. The spatial patterns of the currents induced by the magnetic fields are different from those induced by the electric fields. Electric fields generally are measured in volts per meter and magnetic fields in microtesla (μT) or milligauss (mG) ($1 \mu\text{T} = 10 \text{ mG}$).

- Ambient levels of 60-Hz (or 50-Hz in Europe and elsewhere) magnetic fields in residences and most workplaces are typically 0.01-0.3 μT (0.1-3 mG).

Higher levels are encountered directly under high-voltage transmission lines and in some occupational settings. Some appliances produce magnetic fields of up to 100 μT (1 G) or more in their vicinity. For comparison, the static magnetic field of the earth is about 50 μT (500 mG). Magnetic fields of the magnitude found in residences induce currents within the human body that are generally much smaller than the currents induced naturally from

the function of nerves and muscles. However, the highest field strengths to which a resident might be exposed (those associated with appliances) can produce electric fields within a small region of the body that are comparable to or even larger than the naturally occurring fields, although the magnitude of the largest locally induced fields in the body is not accurately known.

- Human exposure to a 60-Hz magnetic field at 0.1 μT (1 mG) results in the maximum current density of about 1 microampere per square meter ($\mu\text{A}/\text{m}^2$).

The endogenous current densities on the surface of the body (higher densities occur internally) associated with electric activity of nerve cells are of the order of 1 mA/m². The frequencies associated with those endogenous currents within the brain range from less than 1 Hz to about 40 Hz, the strongest components being about 10 Hz. Therefore, the typical externally induced currents are 1,000 times less than the naturally occurring currents.

- Neither experimental nor theoretic data on locally induced current densities within tissues and cells are available that take into consideration the local variations in the electric properties of the medium.

Because the mechanisms through which electric and magnetic fields might produce adverse health effects are obscure, the characteristics of the electric or magnetic fields that need to be measured for testing the linkage of these fields to disease are unclear. In most studies, the root-mean-square (rms) strength of the field, an average field-strength parameter, has been measured on the assumption that this measurement should relate to whatever field characteristics might be most relevant. As noted earlier, wire-code categories have been used in many epidemiologic studies as a surrogate measurement of the actual exposure.

- Exposure levels of electric fields and other characteristics of magnetic fields (harmonics, 1 transients, 2 spatial, and temporal changes) have received relatively little attention.

Very little information is available on the ambient exposure levels to environmental electric fields other than the rms measurements of field strength. Those might vary from 5 to 10 volts per meter (V/m) in a residential setting to as high as 10 kilovolts per meter (kV/m) directly under power transmission lines. Likewise magnetic-field exposures are generally characterized only in terms of their rms field strengths with little or no information on such characteristics as the frequency and magnitude of transients and harmonics. Residential exposures to power-frequency electric and magnetic fields are generally on the order of a few milligauss.

- Indirect estimates of human exposure to magnetic fields (e.g., wiring configuration codes, distance to power lines, and calculated historical fields) have been used in epidemiology. These estimates of magnetic fields correlate poorly with spot measurements of residential 60-Hz magnetic fields, and their reliability in representing other characteristics of the magnetic field has not been established. Because of the many factors that affect exposure levels, great care must be taken in establishing electric-and magnetic-field exposures.
- Unless exposure systems and experimental protocols meet several essential requirements, artifactual results are likely to be obtained in laboratory animal and cell experiments.

Many of the published studies either have used inferior exposure systems and protocols or have not provided sufficient information for their evaluation.

The purpose of studies of in vitro systems is to detect effects of electric or magnetic fields on individual cells or isolated tissues that might be related to health hazards. The conclusions reached after evaluation of published in vitro studies of biologic responses to electric-and magnetic-field exposures are the following:

- Magnetic-field exposures at 50-60 Hz delivered at field strengths similar to those measured for typical residential exposure (0.1-10 mG) do not produce any significant in vitro effects that have been replicated in independent studies.

When effects of an agent are not evident at low exposure levels, as has been the case for exposure to magnetic fields, a standard procedure is to examine the consequences of using higher exposures. A mechanism that relates clearly to a potential health hazard might be discovered in this way.

- Reproducible changes have been observed in the expression of specific features in the cellular signal-transduction pathways for magnetic-field exposures on the order of 100 μ T and higher.

Signal-transduction systems are used by all cells to sense and respond to features of their environments; for example, signal-transduction systems can be activated by the presence of various chemicals, hormones, and growth factors. Changes in signal transduction are very common in many experimental manipulations and are not indicative per se of an adverse effect. Notable in the experiments using high magnetic-field strengths is the lack of other effects, such as damage to the cell's genetic material. With even higher field strengths than those, a variety of effects are seen in cells.

- At field strengths greater than 50 μT (0.5 G), credible positive results are reported for induced changes in intracellular calcium concentrations and for more general changes in gene expression and in components of signal transduction.

No reproducible genotoxicity is observed, however, at any field strength. Again, effects of the sort seen are typical of many experimental manipulations and do not indicate per se a hazard. Effects are observed in very high field-strength exposures (e.g., in the therapeutic use of electromagnetic fields in bone healing).

The overall conclusion, based on the evaluation of these studies, is that exposures to electric and magnetic fields at 50-60 Hz induce changes in cultured cells only at field strengths that exceed typical residential field strengths by factors of 1,000 to 100,000.

Studies of in vivo systems aim to determine the biologic effects of power-frequency electric and magnetic fields on whole animals. Studies of individual cells, described above, are extremely powerful for elucidating biochemical mechanisms but are less well suited for discovering complicated effects that could be related to human health. For such extrapolation, animal experiments are more likely to reveal a subtle effect that might be relevant to human health. The obvious experiment is to expose animals, say mice, to high levels of electric or magnetic fields to observe whether they develop cancer or some other disease. The experiments of this sort that have been done have demonstrated no adverse health outcomes. Such experiments by themselves are inadequate, however, to discount the possibility of adverse effects from electric and magnetic fields, because the animals might not exhibit the same response and sensitivities as humans to the details of the exposure. For that reason, a number of animal experiments have been carried out to examine a large variety of possible effects of exposure. On the basis of an evaluation of the published studies in this area, the committee concludes the following:

- There is no convincing evidence that exposure to 60-Hz electric and magnetic fields causes cancer in animals.

A small number of laboratory studies have been conducted to determine if any relationship exists between power-frequency electric-and magnetic-field exposure and cancer. In the few studies reported to date, consistent reproducible effects of exposure on the development of various types of cancer have not been evident. One area with some laboratory evidence of a health-related effect is that animals treated with carcinogens show a positive relationship between intense magnetic-field exposure and the incidence of breast cancer.

- There is no evidence of any adverse effects on reproduction or development in animals, particularly mammals, from exposure to power-frequency 50- or 60-Hz electric and magnetic fields.
- There is convincing evidence of behavioural responses to electric and magnetic fields that are considerably larger than those encountered in the residential environment; however, adverse neurobehavioral effects of even strong fields have not been demonstrated.

Laboratory evidence clearly shows that animals can detect and respond behaviourally to external electric fields on the order of 5 kV/m rms or larger. Evidence for animal behavioural response to time-varying magnetic fields, up to 3 μ T, is much more tenuous. In either case, general adverse behavioural effects have not been demonstrated.

- Neuroendocrine changes associated with magnetic-field exposure have been reported; however, alterations in neuroendocrine function by magnetic-field exposures have not been shown to cause adverse health effects.

The majority of investigations of magnetic-field effects on pineal-gland function suggest that magnetic fields might inhibit night time pineal and blood melatonin concentrations; in those studies, the effective field strengths varied from 10 μ T (0.1 G) to 5.2 mT (52 G). The experimental data do not compellingly support an effect of sinusoidal electric field on melatonin production. Other than the observed changes in pineal function, an effect of electric and magnetic fields on other neuroendocrine or endocrine functions has not been clearly shown in the relatively small number of experimental studies reported.

Despite the observed reduction in pineal and blood melatonin concentrations in some animals as a consequence of magnetic-field exposure, studies of humans provide no conclusive evidence to date that human melatonin concentrations respond similarly. In animals with observed melatonin changes, adverse health effects have not been shown to be associated with electric-or magnetic-field-related depression in melatonin.

- There is convincing evidence that low-frequency pulsed magnetic fields greater than 5 G are associated with bone-healing responses in animals.

Although replicable effects have been clearly demonstrated in the bone-healing response of animals exposed locally to magnetic fields, the committee did not evaluate the efficacy of this treatment in clinical situations.

IEEE

REF: Standards Coordinating Committee 28. IEEE standard for safety levels with respect to human exposure to electromagnetic fields, 0-3 kHz. New York, NY, IEEE - The Institute of Electrical and Electronics Engineers, 2002 (IEEE Std C95.6-2002). Geneva, World Health Organization, 2007, IARC Working Group

North America

No US federal recommendations exist currently for occupational or residential exposure to 60Hz magnetic fields [64]. The safety level set by the Institute for Electrical and Electronics Engineers (IEEE) include [66, 67]: "The maximum permissible exposure level for the general public to electric fields is 5kV/m, except on transmission line rights-of-way (servitude), where the limit is 10kV/m". "The IEEE Standard explicitly increases the general-public Maximum Permissible Exposure (MPE) level for 60-Hz electric fields from 5 kV/m to 10 kV/m on transmission line rights-of-way. Exposure of the general public would not exceed the MPE of 10 kV/m, except in limited areas under some 765-kV lines". In some states, the maximum permitted fields are the maximum fields that existing lines produce at maximum load.

South Africa

Utilities, in South Africa, involved in the generation and distribution of electrical energy, are bound by the Occupational Health and Safety (OHS) Act [63] to provide such services in a safe manner. There are currently no regulations (under the Hazardous Substances Act) in terms of exposure to power frequency EMF in South Africa and the ICNIRP guidelines are used for assessing human exposure to these fields.

Europe

As far as limits for electric and magnetic field exposure applied in Europe are concerned, the European Standard: EN 50392 [68] is strongly based on the ICNIRP guidelines for exposure power frequency to electric and magnetic fields. From the above, it is noted that utilities are typically guided by a maximum electric field limit of 10kV/m in the design of power lines, particularly 765kV lines. This

maximum electric field limit (10kV/m) is based on safety considerations when a large vehicle (truck) parked underneath the line is touched by a well-grounded (electrically earthed) person, for example. To meet this design limit, particularly for 765kV lines, the required minimum conductor clearance above ground is adjusted accordingly. Safety of the public from electric and magnetic

field exposure is ensured by application of the ICNIRP guidelines, typically at the servitude boundary as residence

within the servitude is generally not allowed. Where exposure to electric and magnetic field levels above the ICNIRP guidelines may take place, special engineering techniques can be applied to reduce the fields to more acceptable levels

7 CONCLUSION

Contents covered by updated references from various organizations as indicated above converges with Dr. PH Pretorius' findings. This concludes that his report is still valid to facilitate environmental impact assessments at Eskom.

Executive Summary

The planning and siting of new power lines involve public participation. In many cases during public meetings and negotiations, the topic of the possible health effects of power frequency electric and magnetic fields surfaces. This report has been prepared, in a not-too-technical manner, in support of questions that may be raised at such meetings. This document could also be included for purposes of additional information in environmental impact assessment reports.

A summary of technical and biological aspects based on a literature survey and field calculations is presented:

Overhead power lines generate electric and magnetic fields. Electric fields, measured in kV/m:

- Are linked to the voltage of the power line and remains relatively stable with the line energized.
- Can be reduced (shielded) fairly easily.
- Decrease with an increase in distance from the line.

Magnetic fields, measured in μT :

- Are linked to the current flowing (load) on the line. Magnetic field levels in the vicinity of a power line typically show daily and seasonal variation patterns.
- Can be reduced. Reducing magnetic fields require special engineering techniques or line designs.
- Decrease with an increase in distance from the line.

As household appliances and other electrical equipment also generate electric and magnetic fields (EMF), people are generally exposed to varying levels of EMF in their daily lives at work and at home.

Many (epidemiology, laboratory and live animal) studies have been conducted over the past three to four decades to determine whether health effects may arise from exposure to EMF. The main focus of the research has been on a possible association between long term exposure to magnetic fields and childhood leukemia. The suggestion for this health outcome stems mainly from some epidemiological studies.

This finding has not been confirmed by controlled laboratory studies: No evidence of a causal relationship between magnetic field exposure and childhood leukemia has been found and no dose-response relationship has been shown to exist between EMF exposure and biological effects.

A possible explanation for the epidemiological findings may be confounding or bias which render the data inconclusive and prevent resolution of the inconsistencies in the epidemiologic data.

Because of the lack of a known biophysical mechanism that would explain these effects, many question the existence of *clinical* responses. *Clinical* responses, if any, as a result of power frequency electric and magnetic field exposure to levels typically found in residential and power line environments, appear insignificant.

The absence of evidence on health effects is generally not considered to mean evidence of the absence of health impacts and has resulted in some scientists advocating caution and finding ways to avoid or reduce exposure.

Studies on behaviour, reproduction, health, meat and milk production have found minimal or no effects of EMF on animals.

Past studies have found no significant effect of EMF on plant growth, crop production and seed germination. No recent studies of plants growing near transmission lines have been conducted.

The guidelines for electric and magnetic field exposure set by the International Commission for Non-Ionising Radiation Protection (ICNIRP) receives world-wide support and are endorsed by the Department of Health in South Africa.

Calculations of electric and magnetic field levels created by overhead power lines have shown that areas where members of the public may be exposed (at the servitude boundary and further away from the line) are well within the ICNIRP guidelines. Where necessary and where field levels exceed the ICNIRP guidelines within the servitude, techniques exist to reduce the field levels.

Nomenclature

Acronyms:

- AC - Alternating Current.
- ELF - Extremely Low Frequency
- EMF - Electric and Magnetic Field.

Units:

- Hz - Herz. 1 Hz = 1 cycle per second.
- kV/m - kilovolt per metre: The unit of measurement of electric field levels (electric field strength). 1kV = one thousand volt per metre.
- μ T - microtesla: The unit of measurement of magnetic field levels (magnetic flux density). 1 μ T = One millionth of a Tesla.
- mG - milligauss: 10 mG = 1 μ T.

Definitions:

- Carcinogen - Cancer causing agent.
- Epidemiology - The study of health and disease in human populations and the factors that affect these.
- Extremely Low Frequency - The frequency range 30 to 300Hz.
- Power Frequency - 50 or 60Hz.
- Precautionary Principle - “When there is threat of serious or irreversible damage:
- uncertainty should not be a reason for postponing action to prevent that damage;
 - precautionary measures should be taken even if cause-and-effect relationships are not clearly established;

Whenever an action or substance could cause irreversible harm, even if that harm is not certain to occur, the action should be prevented and eliminated” [80].

1. INTRODUCTION

1.1 Background and Scope

The planning and siting of new power lines involve public participation. In many cases during public meetings and negotiations, the topic of the possible health effects of power frequency electric and magnetic fields (EMF) surfaces. Empetus Close Corporation has been approached to prepare a report, in a not-too-technical manner, in support of questions that may be raised at such meetings.

Typical questions may include:

- What are electric and magnetic fields?
- How do power line fields compare with fields from other sources?
- What typical field levels are expected for newly planned 400kV and 765kV transmission lines?
- Can field mitigation measures be applied?
- What are the findings of international research on the topic?
- What are the effects of electric and magnetic fields on farm animal fertility?
- What are the effects of electric and magnetic fields on plant growth?
- What are the effects of electric and magnetic fields on milk production?
- How do fields from power lines in South Africa relate to International Standards.

This document could also be included for purposes of additional information in environmental impact assessment reports and based on the typical questions raised above, it was specifically required that the report covers:

- Specific concepts that need to be addressed in forming an understanding of the topic;
- Examples of typical field levels in various environments, including power line environments;
- Findings of studies conducted on health effects of electric and magnetic fields;
- Findings of studies conducted on farm animals and plants near power lines and
- Exposure limits.

Specific notes about the scope:

The intent was not to develop a biological understanding of how exposure to power frequency electric and magnetic fields could produce health effects as this requires a more elaborate report and information relating to this aspect can be found from some of the internet sites sited in Appendix B.

Risk communication, risk management and risk perception did not form part of the original scope of this report.

This report is not an overview of studies but rather a summary of key reviews.

1.2 Approach

The information presented in this report was obtained from a literature survey as well as calculations of electric and magnetic field levels near 400kV and 765kV lines.

In order to meet the requirements for the report outlined above and to address typical questions that may be raised, the report is structured to cover the following sections with most section headings posed as a question:

i. What are Electric and Magnetic Fields?

This section covers the technical aspects and a description of power frequency electric and magnetic fields. Field levels from overhead power lines are compared with field levels encountered in other environments including household appliances. Specific references are cited from which the information was obtained.

ii. Modern Power Line Structures and Associated Electric and Magnetic Fields

Typical field levels and profiles, calculated for modern power line structures based on the technical information (tower geometries and conductor types received from Eskom) presented in Appendix A, are covered in this section. Images of the tower structures are also presented.

iii. What are the Effects on Humans?

In addressing consensus and conclusions drawn from research, it makes sense to reflect on critical, scientific reviews of published research rather than to address and reflect on individual and isolated studies. Reviews as reported by the following organisations, are covered in this section: the Environmental Protection Agency (EPA), the National Radiological Protection Board (NRPB), the National Academy of Science (NAS), the National Institute for Environmental Health Sciences (NIEHS), the International Agency for Research on Cancer (IARC) and the International Commission for Non-Ionizing Radiation Protection (ICNIRP).

iv. What are the Effects on Animals?

This section addresses in particular effects in the context of farm animals. Published reviews covering the effects on farm animals are limited. Only one such review by the US Department of Energy and Bonneville Power Administration (1989) was found in the literature survey and is covered in this report.

v. What are the Effects on Plants?

This section addresses effects mainly in the context of crop farming. Published reviews covering the effects on crops are limited. Only one such review by the US Department of Energy and Bonneville Power Administration (1989) was found in the literature survey and is covered in this report. Findings of studies reported at a seminar later in 1999, generally in support of the findings of the earlier review, are also covered.

vi. Exposure Limits.

Electric and magnetic field levels applied as exposure limits are covered in this Section. The exposure guidelines endorsed by the Department of Health in South Africa are specifically noted.

vii. Can Fields be Reduced?

Based on referenced material, specific measures that can be applied to reduce field levels in the vicinity of power lines are noted.

viii. International Opinion and Consensus.

Opinion on the topic as reflected by the following organisations (in order of publication date) is noted: International Council on Large Electric Systems (CIGRE), the World Health Organisation (WHO), the US National Institute of Environmental Health Sciences (NIEHS) and the National Radiological Protection Board (NRPB) in the United Kingdom.

There are literally thousands of studies that have been published on the topic over the last three to four decades [77, 78]. In order to summarise the findings of research in general and in the context of the questions and sections mentioned, a deliberate attempt was made to rely more on reviews of published research, rather than to cover individual studies only. The author also relied on an internet search (Google Search Engine) to gather information for the report.

The following criteria were used as a guideline for the literature survey:

- Authoritative sources of information of national and international stature were selected as far as possible. Health organisations were preferred. Sources from private organisations were excluded. This applied in particular to the internet search.
- EMF research developed over a period of time and significant advances and improvements in study methodologies and design, in later years, justified the approach to consider mainly material published during the last decade (1996 to 2006).
- Where older material is referenced, it is done:
 - i) because limited or no (review) material was available from the period 1996 to 2006;
 - ii) to demonstrate a specific development of thought or how consensus shifted (if at all) over time.

2. DISCUSSION

2.1 What are Electric and Magnetic Fields?

Electric and magnetic fields (EMF) are always created, in varying levels, with the generation and use of electricity and at the frequency of the electrical power system. In South Africa, as in most European countries, electric power is supplied as an alternating current (AC) at a frequency of 50 Hertz (Hz). This means that the electric current flowing in the system changes direction 50 times per second. The American power system operates at 60 Hz.

Power system frequencies (50 Hz or 60 Hz) are much lower than the frequencies of electromagnetic energy applied, for example, in radio broadcasting (typically 88 to 108 MHz (1 MHz = 1 million Hertz)) or microwave systems operating at 2,4 GHz (1 GHz = 1 billion Hertz). This is important to note when discussing biological effects. Any biological effects that may occur from exposure to microwave frequencies will be as a result of heating of biological tissue. Safety precautions, for this frequency range, are thus based on limiting field levels that may cause a rise in tissue temperature.

Any biological effects associated with exposure to power frequency EMF, occur as a result of electric current induced in the subject by the EMF. Safety precautions, for these frequencies are thus based on limiting field levels that may induce electric current in the subject that are considered harmful.

At the low frequency of 50 Hz or 60 Hz, two fields exist that can be studied separately: electric fields and magnetic fields.

Electric fields are produced by the presence of electric charges and therefore the Voltage (V) applied to a conductor. Generally the voltage on a system is stable and remains the same. Electric fields decrease with an increase in distance from the source (conductor).

Electric field levels are measured in Volts per metre (V/m). Because of the range of the levels encountered in power system environments, field levels are reported in kilovolt per metre (kV/m). (One thousand V/m = 1 kV/m).

Magnetic fields are produced by the current flowing (movement of electric charge) on a conductor. Electric current is measured in Ampere (A). The current on a system may vary depending on the number of devices (load) supplied by the system. As the load changes, the magnetic field will change. Magnetic fields decrease with an increase in distance from the source (conductor).

Magnetic field levels are measured in Tesla (T). Because of the range of the levels encountered in typical power system environments, field levels are reported in microtesla (μT). (One millionth of a Tesla = 1 μT). Some American literature use the unit of Gauss (G) where 10 milligauss (mG) = 1 μT .

Electric fields at 50 Hz are easily shielded by conducting objects. Reducing magnetic fields (at 50 Hz) requires special engineering techniques or designs and are treated in Section 2.7 of this report.

Electric and magnetic fields may exist alone or in combination. For example, an electric field will be created around the electric lead of a lamp plugged into and

switched on at the wall, with the device switched off (light off). Should the lamp be switched on at the wall and at the device (light on), electric current will flow and a magnetic field will co-exist with the electric field in the vicinity of the electric lead. This field effect is the same for power lines.

Table 1 summarises typical electric field levels encountered in various environments and close to household appliances [1].

Table 1: Summary of typical electric field levels encountered in various environments and close to household appliances [1].

Description	Electric Field (V/m)
Directly below 400kV power line at ground level.	10,000
25m from centre line of 400kV power line.	1,000
Near typical domestic appliances.	10 - 250
Typical field level in homes.	1 - 10
Outside homes.	Less than 1

On a calm, clear and sunny day, the natural electric field could be a few tens of V/m. This level can increase to several thousand V/m during a thunderstorm.

Table 2 summarises typical electric field levels measured in the vicinity of Eskom power lines [2].

Table 2: Summary of typical electric field levels measured in the vicinity of Eskom power lines [2].

Voltage (kV)	Max Electric Field (V/m)	Electric Field at Servitude Boundary (V/m)	Servitude Width (m) ⁽¹⁾
765	7,000	2,500	40,0
400	4,700	1,500	23,5
275	3,000	500	23,5
132	1,300	500	15,5

⁽¹⁾ Measured from the centre of the line.

From Table 2 it is clear that the electric field falls to lower levels with an increase in distance from the line.

Table 3 summarises typical magnetic field levels encountered in various environments and close to household appliances [1].

Table 3: Summary of typical magnetic field levels encountered in various environments and close to household appliances [1].

Description	Magnetic Field (μT)
Directly below 400kV power line at ground level.	40
25m from centre line of 400kV power line.	8
Directly below 132kV power line at ground level.	7
25m from centre line of 132kV power line.	0,5
Vacuum cleaner, electric drill.	2 - 20
Food mixer.	0,6 - 10
Hair dryer.	0,01 - 7
Dish washer.	0,6 - 3
Washing machine.	0,15 - 3
Fluorescent lamp.	0,15 - 0,5
Ambient field inside homes.	0,01 - 0,2

Note: Levels indicated for household appliances were measured at 30cm from the appliance.

From Table 3 it can be seen that appliances, particularly those with electric motors, may generate magnetic fields with levels similar to power lines. Exposure to fields from household appliances is usually of a short duration.

The natural magnetic field is of the order of $30\mu\text{T}$ (in Johannesburg) and may vary up to about $70\mu\text{T}$ at the poles (North or South pole). This field is static and varies very slowly with time.

Table 4 summarises typical magnetic field levels measured in the vicinity of Eskom power lines [2].

Table 4: Summary of typical magnetic field levels measured in the vicinity of Eskom power lines [2].

Voltage (kV)	Current (A)	Max Magnetic Field (μT)	Magnetic Field at Servitude Boundary (μT)	Servitude Width (m) ⁽¹⁾
765	560	6,0	1,5	40,0
400	650	10,5	2,5	23,5
275	350	6,0	1,0	23,5
132	150	4,0	1,0	15,5

⁽¹⁾ Measured from the centre of the line.

It is clear from Table 4 that the magnetic field falls to lower levels with an increase in distance from the line.

2.2 Modern Power Line Structures and Associated Electric and Magnetic Fields

In discussing electric and magnetic fields from overhead power lines it is useful to refer to the maximum field level below the line as well as the field level at the servitude boundary. Maximum field levels are found at the midspan position (the position midway between two adjacent towers), where the conductors are closest to the ground.

Electric fields created in the vicinity of overhead power lines depend on the voltage on the line, the tower configuration and the conductor height above ground.

Magnetic fields created in the vicinity of overhead power lines depend on the current flowing on the line, the tower configuration and the conductor height above ground.

Table 5 illustrates some of the existing and newer line designs used by Eskom at 400 kV and 765 kV. Typical electric and magnetic field profiles associated with these designs are indicated in Figures 1 to 4. For the field calculations, the lowest conductor was kept at the same height for all three configurations considered: 17 m above ground for 765 kV and 13 m above ground for 400 kV. Refer to Appendix A for more detail on the line configurations used in the field calculations.

The magnetic field profiles in all cases were calculated for a line current of 1,000 A. Because the magnetic field is directly proportional to the line current, the field value can easily be scaled up or down for different loads on the line.

The zero metre mark '0 m' in Figures 1 to 4 indicates the centre of the line.

It is clear from the field profiles in Figures 1 to 4 that different tower configurations present different field profiles. Power line design engineers use this as a technique in the design of overhead power lines to arrive at the lowest and desired field levels in the vicinity of a power line. It should be noted that electric and magnetic field levels are not the main consideration in the design of an overhead power line, but that other parameters related to the geometry (conductor type, placement of shield wires and phase spacing, for example) play a significant part in the design of the line in order to optimize its electrical performance and to minimise cost.

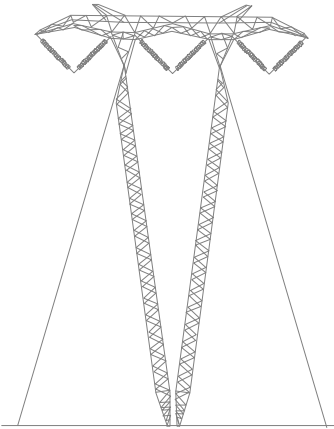

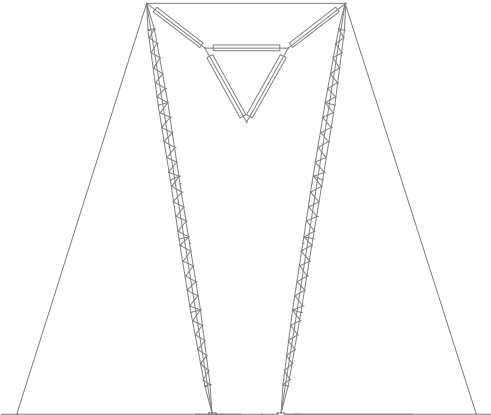

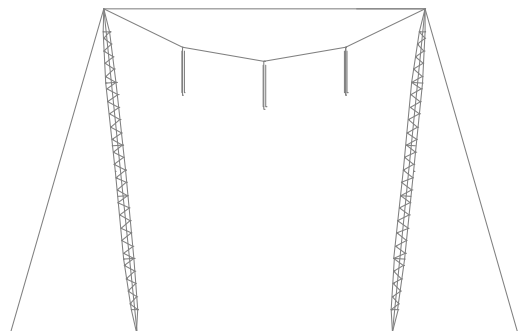

In some instances, power lines may be constructed to run parallel to each other. Electric and magnetic field profiles of an example of two 765 kV lines running parallel to each other (60 m centre to centre spacing) are respectively indicated in Figure 5 and Figure 6. In this case the centres of the towers are located at -30 m and 30 m in Figures 5 and 6.

From Figure 2 it can be observed that the maximum magnetic field level for the 400 kV designs, is higher than the maximum magnetic field level for the 765 kV designs. This is because the height of the conductors, in the case of the 400 kV designs, is lower than that for the 765 kV designs. In both cases the line current was 1,000 A.

The profiles indicated in Figures 1 to 6 show how the field levels fall to lower values with increasing distance from the line. Maximum allowable field levels used in the design of overhead power lines are covered in Section 2.6.

Although specific tower designs can be selected to reduce maximum field levels, if required, field reduction is not the main consideration in the selection of a specific tower type. Techniques, other than tower configuration, to reduce field levels are covered in Section 2.7.

2.3 What are the Effects on Humans?

2.3.1 Background

There are different types of studies addressing distinct aspects of the problem and essential in evaluating potential adverse health effects of electric and magnetic fields.

Laboratory studies are conducted on cells (removed from the organism) and are designed to reveal fundamental underlying mechanisms involved in linking EMF exposure to biological effects. The focus is on changes, at cellular and molecular level, brought about by exposure to the field. Changes observed may provide clues to how a physical force brings about a biological action in the body. Possible compensation mechanisms may be inhibited during this type of study as the cells are not in their normal living environment.

Whole animal studies involve live animals, are more closely related to situation in real life and may provide evidence more relevant to establishing safe exposure levels for humans. Different exposure levels are employed in the study to yield information about dose-response relationships.

Epidemiological studies (human health studies) provide information on long-term effects of exposure. These studies investigate the occurrence and distribution of diseases, in real life situations, in human populations. Researchers can then establish if there is a statistical association between exposure to EMF and the incidence of a specific disease or adverse health effect.

Epidemiological studies involve measurements on very complex human populations. In addition, epidemiological studies are difficult to control well to detect small effects and factors, such as, confounding may play a part in affecting the outcome of the study. For these reasons, scientists evaluate all relevant evidence from cellular studies, animal studies and epidemiological studies when deciding about potential health hazards from EMF.

Of the first reports covering possible effects of electric fields were published in the sixties [3]. These reports noted Russian substation workers complaining about fatigue and reduced sexual potency and claimed these effects to result from exposure to electric fields in the substations.

The debate on possible health effects of exposure to power frequency magnetic fields was stimulated by the first epidemiological study [4], published by Wertheimer and Leeper in 1979, that suggested a possible association between long term exposure to power line magnetic fields and leukemia in children.

Most of the reports suggesting a possible association between some childhood cancers and exposure to EMF are based on epidemiological studies. The findings of the epidemiological studies suggesting such an association have not been confirmed by controlled laboratory studies. The controversy around the topic was stimulated by the latter as well as certain aspects related to epidemiology that included:

- In epidemiology, an agent (for example, EMF) may have an association or correlation with an event (for example, leukemia) but association does not necessarily indicate a cause-effect relationship.
- The association indicated by some epidemiological studies, if it existed, was small.
- The number of cases in some of these studies was small.

Many studies on the topic of electric and magnetic fields and possible health effects have been reported on over the last two decades [5, 6, 77, 78]. Some of these studies, from a scientific perspective, have been of a higher quality and have been designed and executed in more credible ways than others. In addressing consensus and conclusions drawn from this research, it makes sense to reflect on critical, scientific reviews of published research rather than to address and reflect on individual and isolated studies. Reviews reported by the following organisations, are noted in order of publication date:

- Environmental Protection Agency (EPA), 1990 [7];
- National Radiological Protection Board (NRPB), 1992 [8];
- National Academy of Science, 1996 [9];
- National Institute for Environmental Health Sciences (NIEHS), 1999 [10,11,12];
- National Radiological Protection Board (NRPB), 2001 [14];
- International Agency for Research on Cancer (IARC), 2001 [15];
- International Commission for Non-Ionizing Radiation Protection (ICNIRP), 2001 [79];

2.3.2 Environmental Protection Agency (EPA), 1990 [7].

“In evaluating the potential for carcinogenicity of chemical agents, EPA has developed an approach that attempts to integrate all of the available information into a summary classification of the weight of evidence that the agent is carcinogenic in humans. At this time, such a characterisation regarding the link between cancer and exposure to EMF fields is not appropriate because the basic nature of the interaction between EM fields and biological processes leading to cancer is not understood.”

“With our current understanding, we can identify 60 Hz magnetic fields from power lines and perhaps other sources in the home as a possible, but not proven, cause of cancer in people.”

“The absence of key information summarised above makes it difficult to make quantitative estimates of risk. Such quantitative estimates are necessary before judgments about the degree of safety or hazard of a given exposure can be made. This situation indicates the need to continue to evaluate the information from ongoing studies and to further evaluate the mechanisms of carcinogenic action and the characteristics of exposure that lead to these effects.”

2.3.3 National Radiological Protection Board (NRPB), 1992 [8].

“In summary, the epidemiological findings that have been reviewed provide no firm evidence of the existence of a carcinogenic hazard from exposure of paternal gonads, the fetus, children, or adults to the extremely low frequency electromagnetic fields that might be associated with residence near major sources of electricity supply, the use of electrical appliances, or work in the electrical, electronic, and telecommunications industries. Much of the evidence that has been cited is

inconsistent, or derives from studies that have been inadequately controlled, and some is likely to have been distorted by bias against the reporting or publishing of negative results. The only finding that is at all notable is the consistency with which the least weak evidence relates to a small risk of brain tumours. This consistency is, however, less impressive that might appear as brain tumours in childhood and adult life are different in origin, arising from different types of cell. In the absence of any unambiguous experimental evidence to suggest that exposure to these electromagnetic fields is likely to be carcinogenic, in the broadest sense of the term, the findings to date can be regarded only as sufficient to justify formulating a hypothesis for testing by further investigation.”

2.3.4 National Academy of Sciences, 1996 [9].

“Based on a comprehensive evaluation of published studies relating to the effects of power frequency electric and magnetic fields on cells, tissues, and organisms (including humans), the conclusion of the committee is that the current body of evidence does not show that exposure to these fields presents a human-health hazard. Specifically, no conclusive and consistent evidence shows that exposure to residential electric and magnetic fields produce cancer, adverse neurobehavioral effects, or reproductive and developmental effects.”

2.3.5 National Institute of Environmental Health Sciences (NIEHS), 1999 [10,11,12].

Table 6 summarises the conclusions drawn by the NIEHS Working group on non-cancer related health effects.

NIEHS concluded the following in terms of cancer:

"The NIEHS believes that the probability that EMF exposure is truly a health hazard is currently small. The weak epidemiological associations and lack of any laboratory support for these associations provide only marginal scientific support that exposure to this agent is causing any degree of harm."

NIEHS noted that the "strongest evidence" for health effects comes from statistical associations observed in human populations with childhood leukemia. "While the support from individual studies is weak," according to the report, "these epidemiological studies demonstrate, for some methods of measuring exposure, a fairly consistent pattern of a small, increased risk with increasing exposure that is somewhat weaker for chronic lymphocytic leukemia than for childhood leukemia."

NIEHS further noted that laboratory studies focusing on basic biological function do not support the findings of the epidemiological associations and "Virtually all of the laboratory evidence in animals and humans and most of the mechanistic studies in cells fail to support a causal [cause and effect] relationship."

The panel assisting NIEHS in reaching its conclusions, rejected EMF as a "known" or proven, or even "probable" carcinogen. A majority of the panel said a role in cancer could not be ruled out and EMF should be regarded as "possible" carcinogen. The NIEHS recommended that electric and magnetic fields be treated as a "possible" cancer causing agent, but emphasised the weakness of the data and the low risk that may be involved.

Table 6. Conclusions drawn by the NIEHS Working group on non-cancer related health effects.

Biological Parameter / Health Outcome	Evidence Supporting Biological Parameter / Health Outcome			
	Strong	Weak	Inadequate	None
Adverse birth outcomes from maternal occupational exposure.			X	
Reproductive effects from paternal exposure.			X	
Alzheimer's disease.			X	
Amyotrophic lateral sclerosis.			X	
Suicide and depression.			X	
Adverse effects on pregnancy outcome or depression.			X	
Effects on immune system in experimental animals.				X
Cardiovascular disease.			X	
Effects on hematological parameters in rodents.				X
Neurobehavioral, neuropharmacological, neurophysiological and neurochemical effects in experimental animals.		X		
Reproductive or developmental effects from exposure to sinusoidal magnetic fields in experimental animals.				X
Affects bone repair and adaptation – strong evidence for complex clinical exposures to pulsed electromagnetic fields.	X			
Affect nervous system and non-bone connective tissue repair and adaptation in vertebrates – no conclusion reached.				
Short term exposure and heart rate variability.		X		
Short term exposure and changes in sleep disturbance.		X		
Short term exposure and suppression of melatonin.		X		
Alters the levels of melatonin in rodents.		X		
Alters the levels of melatonin in sheep and baboons.				X
Effects on hematological system in experimental animals.				X
Electric fields can be perceived.	X			

2.3.6 National Radiological Protection Board (NRPB), 2001 [14].

“Studies reviewed in the earlier report [1992] by the Advisory Group suffered from a lack of measurement-based exposure assessments. Since then, considerable advances have been made in methods for assessing exposure, both in the case of experimental studies and in epidemiological investigations. Instrumentation allowing personal exposure to be measured has become widely available and has been used in many of the more recently published studies. This has provided a substantially improved basis for many of the epidemiological studies reviewed by the Group. “

“At the cellular level, there is no clear evidence that exposure to power frequency electromagnetic fields at levels that are likely to be encountered can affect biological processes. Studies are often contradictory and there is a lack of confirmation of

positive results from different laboratories using the same experimental conditions. There is no convincing evidence that exposure to such fields is directly genotoxic nor that it can bring about the transformation of cells in culture and it is therefore unlikely to initiate carcinogenesis.”

“Those results that are claimed to demonstrate a positive effect of exposure to power frequency magnetic fields tend to show only small changes, the biological consequences of which are not clear.”

“Overall, no convincing evidence was seen from a review of a large number of animal studies to support the hypothesis that exposure to power frequency electro-magnetic fields increases the risk of cancer.”

“Recent large and well-conducted studies have provided better evidence than was available in the past on the relationship between power frequency magnetic field exposure and the risk of cancer. Taken in conjunction they suggest that relatively heavy average exposures of 0,4 μT or more are associated with a doubling of the risk of leukaemia in children less than 15 years of age. The evidence is, however, not conclusive. In those studies in which measurements were made, the extent to which the more heavily exposed children were representative is in doubt, while in those in Nordic countries in which representativeness is assured, the fields were estimated and the results based on such small numbers that the findings could have been due to chance. In the UK, very few children (perhaps 4 in 1000) are exposed to 0,4 μT or more and a study in the UK, with much the largest number of direct measurements of exposure, found no evidence of risk at lower levels. Nevertheless, the possibility remains that high and prolonged time-weighted average exposure to power frequency magnetic fields can increase the risk of leukaemia in children. Data on brain tumours come from some of the studies also investigating leukaemia and from others concerned exclusively with these tumours. They provide no comparable evidence of an association. There have been many fewer studies in adults. There is no reason to believe that residential exposure to electromagnetic fields is involved in the development of leukaemia or brain tumours in adults.”

“Laboratory experiments have provided no good evidence that extremely low frequency electromagnetic fields are capable of producing cancer, nor do human epidemiological studies suggest that they cause cancer in general. There is, however, some epidemiological evidence that prolonged exposure to higher levels of power frequency magnetic fields is associated with a small risk of leukaemia in children. In practice, such levels of exposure are seldom encountered by the general public in the UK. In the absence of clear evidence of a carcinogenic effect in adults, or of a plausible explanation from experiments on animals or isolated cells, the epidemiological evidence is currently not strong enough to justify a firm conclusion that such fields cause leukaemia in children. Unless, however, further research indicates that the finding is due to chance or some currently unrecognised artefact, the possibility remains that intense and prolonged exposures to magnetic fields can increase the risk of leukaemia in children.”

2.3.7 International Agency for Research on Cancer (IARC), 2001 [15].

“IARC has now concluded that ELF magnetic fields are possibly carcinogenic to humans, based on consistent statistical associations of high level residential magnetic fields with a doubling of risk of childhood leukaemia. Children who are exposed to

residential ELF magnetic fields less than 0,4 microtesla have no increased risk for leukaemia.”

”However, pooled analyses of data from a number of well-conducted studies show a fairly consistent statistical association between a doubling of risk of childhood leukaemia and power-frequency (50 or 60 Hz) residential ELF magnetic field strengths above 0,4 microtesla. In contrast, no consistent evidence was found that childhood exposures to ELF electric or magnetic fields are associated with brain tumours or any other kinds of solid tumours. No consistent evidence was found that residential or occupational exposures of adults to ELF magnetic fields increase risk for any kind of cancer.”

”Studies in experimental animals have not shown a consistent carcinogenic or co-carcinogenic effects of exposures to ELF magnetic fields, and no scientific explanation has been established for the observed association of increased childhood leukaemia risk with increasing residential ELF magnetic field exposure.”

2.3.8 International Commission for Non-Ionizing Radiation Protection (ICNIRP), 2001 [79].

“We reviewed the now voluminous epidemiologic literature on EMF and risks of chronic disease and conclude the following:

- a) The quality of epidemiologic studies on this topic has improved over time and several of the recent studies on childhood leukemia and on cancer associated with occupational exposure are close to the limit of what can realistically be achieved in terms of size of study and methodological rigor.
- b) Exposure assessment is a particular difficulty of EMF epidemiology, in several respects:
 - i) The exposure is imperceptible, ubiquitous, has multiple sources, and can vary greatly over time and short distances.
 - ii) The exposure period of relevance is before the date at which measurements can realistically be obtained and of unknown duration and induction period.
 - iii) The appropriate exposure metric is not known and there are no biological data from which to impute it.
- c) In the absence of experimental evidence and given the methodological uncertainties in the epidemiologic literature, there is no chronic disease for which an etiological relation to EMF can be regarded as established.
- d) There has been a large body of high quality data for childhood cancer, and also for adult leukemia and brain tumor in relation to occupational exposure. Among all the outcomes evaluated in epidemiologic studies of EMF, childhood leukemia in relation to postnatal exposures above 0.4 μT is the one for which there is most evidence of an association. The relative risk has been estimated at 2.0 (95% confidence limit: 1.27–3.13) in a large pooled analysis. This is unlikely to be due to chance but, may be, in part, due to bias. This is difficult to interpret in the absence of a known mechanism or reproducible experimental support. In the large pooled analysis only 0.8% of all children were exposed above 0.4 μT . Further

studies need to be designed to test specific hypotheses such as aspects of selection bias or exposure.”

2.3.9 Review of Epidemiology and Childhood Leukemia, 2006 [16].

A review of epidemiology of childhood leukemia and residential exposure to magnetic fields concluded: "The recent studies, using the exposure methods and the cut-off levels set a priori, each concluded that there was little evidence of any association. The pooled analyses, using different exposure measures and different cut-offs, conclude that an association exists at high exposure levels. It is not clear if the results of the pooled analysis are more valid than those of the recent major studies, although this has been often assumed in influential reviews."

2.3.10 Review of Studies on Breast Cancer, 2006 [17].

“Following a thorough review of the published scientific literature, the report concludes that overall the evidence does not support the hypothesis that exposure to EMF are associated with an increased risk of breast cancer. In addition, EMF do not appear to affect the production or biological action of the hormone melatonin.”

2.3.11 Review of Electromagnetic Hypersensitivity, 2005 [18].

Electromagnetic hypersensitivity is a term used for symptoms claimed to be related to electric and magnetic field exposure. Symptoms most commonly experienced include redness, tingling and burning sensations of the skin as well as fatigue, tiredness, concentration difficulties, dizziness, nausea, heart palpitation and digestive disturbances.

Based on a Workshop on Electromagnetic Hypersensitivity organised by the World Health Organisation and held in 2004, an international conference on the topic (1998), a European Commission report (1997) and recent reviews of related literature, WHO concluded as follows [18]:

“Electromagnetic Hypersensitivity (EHS) has no clear diagnostic criteria and there is no scientific basis to link EHS symptoms to EMF exposure. Further, EHS is not a medical diagnosis, nor is it clear that it represents a single medical problem.”

2.3.12 Pacemakers [19, 20]

Magnetic fields of the order of 100 μ T and higher can cause intermittent mode reversion or pacing inhibition in patients with unipolar sensing pacemakers. The overall incidence of this interference is low with more modern pacemakers and depends on the situation of each individual. Electric fields have been shown to affect the older type of pacemakers [19].

Persons wearing pacemakers that may be exposed to power line EMF are advised to consult a physician regarding their individual situations.

Summary

In summary, the following is noted in terms of present knowledge on the possible health effects of EMF:

- The main focus of research has been on a possible association between long term exposure to magnetic fields and childhood leukemia.
- Based on the epidemiological findings, the risk of EMF being a health hazard is small.
- Based on current understanding of the topic, EMF is regarded a possible but not proven cause of cancer.
- The suggestion for this health outcome stems mainly from a fairly consistent pattern of the increased but small risk observed from some epidemiological studies. This finding has not been confirmed by (notably all) controlled laboratory studies.
- No evidence of a causal relationship between magnetic field exposure and childhood leukemia has been found and no dose-response relationship has been shown to exist between EMF exposure and biological effects.
- A possible explanation for the epidemiological findings may be confounding (a factor other than EMF) or bias (subjects studied are not representative of the target population about which conclusions are drawn) which render the data inconclusive and prevent resolution of the inconsistencies in the epidemiologic data.

2.4 What are the Effects on Animals?

Table 7 summarises the findings of studies done on animals near overhead power lines. Studies typically involve the comparison of an exposed group versus a control group or the energisation and de-energisation of a line for some period of time.

See Notes 2 and 3 at the end of Table 7 for information about fish and bees.

Table 7: Effects of electric and magnetic fields on animals.

No	Study	Finding/s	Reference/s
1.	Livestock near overhead power lines.	Experience from electric utilities and results from research show in general that electric fields from overhead power lines do not affect behaviour or health of livestock. Livestock of all kinds often rest or feed underneath power lines.	[19, 21]

No	Study	Finding/s	Reference/s
2.	Live stock living near a 765kV line.	A comprehensive study on livestock (beef and dairy cattle, sheep, hogs and horses) living on eleven farms and near a 765kV line showed no evidence that the health, behaviour or performance of the livestock were affected by electric fields. The 765kV line produced electric fields on some of the farms up to 12kV/m.	[19, 22]
3.	Milk production on of dairy cattle near 765kV lines.	From a 6 year long study on 55 dairy farms located near 765kV lines, no indication was found that the presence of the power lines developed any long-term effects on milk production.	[19, 23]
4.	Fertility of cattle near 400kV lines.	<p>No effects on cattle fertility were noted in pilot studies of 36 herds, during which artificial insemination was applied, near 400kV lines.</p> <p>A larger study involving 106 farms in Sweden did not show cows to have decreased fertility. On average, they were exposed to the 400kV lines for more than 15 days per year and to maximum electric fields of 5kV/m on some of the farms.</p> <p>An experimental study showed the fertility parameters of 58 cows studied, were not affected by exposure to a 400kV line. Breeding was achieved by artificial insemination and the fertility parameters included: estrous cycle, number of inseminations per pregnancy and conception rate. The animals were exposed for 120 days to 50Hz electric fields of 4kV/m (average) and magnetic fields of 2µT (average).</p>	[19, 24, 25, 26]

No	Study	Finding/s	Reference/s
5.	Behaviour, performance and reproduction of swine raised beneath a 345kV line.	Swine raised on purpose beneath a 345kV power line were exposed to a maximum electric field of 4,2kV/m. A study of their behaviour and performance showed no effects related to field exposure on their body weight, carcass quality, behaviour or feed intake. Findings on reproduction, the second phase of the study, showed no effect of the line on pregnancy rate, frequency of birth defects or weight gain of the young.	[19, 27, 28]
6.	Behaviour of cattle near a 1,200kV line.	<p>Cattle behaviour was studied near a 1,200kV prototype line during the summers over a 5 year period. A 12kV/m maximum electric field was created by the line.</p> <p>Animals showed no reluctance to graze or drink underneath the line. Statistical analysis of data from the two first years of the study indicated that the cattle spent somewhat more time near the line when de-energised. This finding could not conclusively be related to the line.</p> <p>Apart from one animal that died of a bacterial infection, the other animals studied during the 5 year period, remained healthy with no abnormal conditions noted.</p>	[19, 29]
7.	Immune function of sheep living near a 500kV line.	No evidence of differences in the measures of immune function was found in the final analysis of the sheep exposed for 27 months to mean electric and magnetic field levels respectively of 5,2 to 5,8kV/m and 3,5 to 3,8 μ T.	[30]

No	Study	Finding/s	Reference/s
8.	Wild animals near overhead power lines.	<p>Research suggests that any effects of electric and magnetic fields on wildlife are subtle and difficult to identify.</p> <p>Based on studies with laboratory animals, wildlife may be able to detect electric fields through such means as hair stimulation. Research has not shown these fields to adversely affect wildlife behaviour or health.</p>	[19, 31, 32]
9.	Wild animals near a 500kV line.	No apparent effects were observed from electric or magnetic fields of a 500kV line on the movement of deer and elk. Some animals were attracted to the cleared servitude for feeding. Game tended to avoid the servitude and similar bush clearings during daytime during the hunting season.	[19, 33]
10.	Small mammals near 500kV lines.	<p>A study on the effect of two 500kV lines passing through a servitude showed small mammals to be more abundant in the cleared servitude in hardwood forests as opposed to pine forests. In both areas, the servitude was used by some species not present in the adjacent forest.</p> <p>The study indicated the use of the various areas by the small mammals to be strongly influenced by vegetation composition and distribution that in turn relate to cover and availability of food.</p>	[19, 34]

No	Study	Finding/s	Reference/s
11.	Small mammals near a 1,200kV line.	A study over several years did not show any adverse effects on the mammals.	[19, 35, 36]
12.	General farm investigations.	“Several large investigations have been carried out on livestock living under and near high voltage power lines. No significant effects on fertility, growth or milk production have been found.”	[76]
13.	Birds near power lines. (Considerations other than electric and magnetic fields arise in the context of birds and power lines – see Note 1 below).	<p>Studies of song birds near overhead power lines indicate that vegetation within the servitude is the primary factor influencing usage and behaviour, rather than electric or magnetic fields.</p> <p>A study on hawks nesting in towers of 500kV and 230kV energized power lines have shown that about the same average number of young were produced as were reported for hawks nesting in trees and cliffs.</p> <p>There is no evidence known of that suggest overhead power lines are disrupting the migratory flight of birds.</p>	[19, 35, 37, 38, 39]
14.	Birds near 765kV line. (Considerations other than electric and magnetic fields arise in the context of birds and power lines – see Note 1 below).	A laboratory study designed to mimic exposure to the 10kV/m electric field of a 765kV line, has shown a reduction in hatching success and increase in egg size, fledging success, and embryonic development of American kestrels.	[40]

Notes : 1) In open country, some bird species may use the towers for perching and nesting. The Environmental Management Programmes employed by electric utilities make provision for birds and power lines. These include: Marking of power line conductors to make them more visible to birds;

Specially designed and modified power lines and towers to reduce the possibility of bird collision and electrocution.

The details of these fall outside the scope of this report and the reader is referred to the local electric utility for more information on these aspects [2]. Research on bird collisions does not suggest that electric or magnetic fields cause disorientation of flying birds. Electrocution of birds with large wingspans is generally associated with distribution lines with relatively small phase spacing and not with electric or magnetic field exposure.

- 2) Some fish species are sensitive to very weak, low frequency electric and magnetic fields in water. American eels and Atlantic salmon have been reported to perceive low frequency electric fields of between 7 and 70mV/m (millivolt per meter) [41]. A study on electric fields up to 20mV/m (45Hz to 75Hz), however, showed “little, if any effect on behaviour of blue-gill fry” [19, 41, 42].
- 3) Although not generally reported by beekeepers, studies have shown power line electric fields can affect honey bee colonies [19, 43]. The effects are most likely caused by micro-shocks experienced by the bees whilst inside the hive. Magnetic fields appear to have no significant effect on bees. No effects were reported for bees flying in an electric field of 11kV/m. In preventing the mentioned effect, it is recommended that bee hives be placed outside the servitude. Alternatively, should bee hives need to be placed inside the servitude, techniques to shield the bees from the power line electric field should be applied. For example, earthing the metal hive lid or introducing an earthed, wire screen over the hives.
- 4) For findings of specific laboratory studies on plant and animal cell cultures, the reader is referred to Reference [5] and [6] and some of the relevant Internet sites in Appendix B.

Summary

In general, studies of animal reproductive performance, behaviour, milk production, meat production, health and navigation have found minimal or no effects of EMF. The literature published to date has shown little evidence of adverse effects of EMF from overhead power lines on farm animals and wildlife.

2.5 What are the Effects on Plants?

The effects of electric fields on plants have been a field of interest to scientists since the eighteenth century, mainly because of interest in possible use of electricity to increase crop yield [19]. During the mid nineteen seventies, some EMF studies were specifically directed towards investigations on the effects of power frequency *electric* fields on plants. These were later followed by effects of *magnetic* fields on plants. Table 8 summarises the findings of some of these studies.

Table 8: Effects of electric and magnetic fields on plants.

No	Study	Findings/s	Reference/s
1.	Eighty five plants species were studied in a laboratory exposed to electric fields up to 50kV/m. In addition, crops (including corn and wheat) grown in a greenhouse, exposed to a 30kV/m electric field.	Some species with sharp pointed leave tips shown minor tip damage starting to occur at electric field levels of 15 to 20kV/m (Note 1). This effect was not observed on plants with rounded leaf tips, even at 50kV/m. Germination, plant growth and productivity were not affected at these high levels.	[19, 44, 45]
2.	Corn and other crops growing near 765kV lines, including a test line, producing electric field levels respectively up to 12kV/m and 16kV/m.	The overall results showed no noticeable influence on crop growth and productivity. Some crops growing in the 16kV/m field of the test line showed some leaf tip damage. Overall plant growth was, however, not impaired.	[19, 46, 47, 48, 49, 50]
3.	Corn grown in electric field beneath a 500kV line.	Corn grown in the electric field up to 8,5kV/m showed a lower yield when compared to corn grown in areas shielded from the electric field. Other crops and trees that included cotton, soybeans, clover, poplar and pine showed no effects. The researchers concluded that “data for the corn study was insufficient to reach definite conclusions and that further investigation was warranted”.	[19, 51]
4.	Crops grown near a 500kV transmission line.	No differences in yields of soybeans and rice were noted between that growing under the line and that growing away from the line. A lower cotton yield (about fifteen percent) was found under the line. “The authors could not determine whether the effect was related to electric or magnetic fields or to ineffective aerial application of agricultural chemicals to crops near the line.”	[19, 52]

No	Study	Finding/s	Reference/s
5.	Plants (trees, shrubs, grasses and crops) growing near a 1,200kV prototype line.	<p>The tips of branches of some trees that were planted below the line and left to grow on purpose (as close as 12m from the line) were damaged by corona (See Note 1).</p> <p>Shrubs growing beneath the line were not affected.</p> <p>Weather and natural variability caused significant differences in crop production over a five year period. During this time, with an electric field ranging between 7 and 12kV/m, no consistent differences were noted to indicate the 1,200kV line affected plant growth.</p> <p>No effects could be related to the line on pea and barley seeds during germination studies.</p> <p>Pasture grass growing beneath the line was not inhibited by electric fields up to 12kV/m.</p>	[19, 29, 35, 36, 53]
6.	Wheat growing in pots below a test line producing a 7,7kV/m electric field.	No effects were observed on wheat growth.	[19, 54]
7.	General farm investigations.	“Various field studies have shown that power line fields do not affect the growth of crops and other low-growing vegetation. The tips of tree branches allowed to grow near the conductors can be damaged by the corona discharge induced by strong electric fields, although overall tree growth and survival appeared unaffected”.	[76]

No	Study	Finding/s	Reference/s
8.	Germination of seeds exposed to 50 μ T magnetic fields at extremely low frequency.	Some authors reported on the enhancement of seed germination from exposure to 50 μ T magnetic fields. The mechanism for this effect is not understood and other investigators have been unable to confirm this finding.	[55, 56, 57, 58]
9.	Crop performance of crops grown beneath high voltage power lines in electric fields up to 12,5kV/m.	The studies reported small, if any effects.	[55, 59]
10.	Corn and wheat grown in electric fields up to 3,9kV/m and magnetic fields up to 4,5 μ T in plots at varying distance near a 380kV line. The study was done over a four year period.	The researchers found “some evidence for some physiological reactions in response to the effects of field strength. However, the variations were not statistically significant, showed no apparent relation to the field strength, and were comparable to small-scale effects due to differences in soil texture between the plots. Thus, if the study did uncover effects of environmental electric and magnetic fields at these levels, they were minor in nature.”	[55, 60]

Notes: 1) Any object placed in an electric field will disturb (enhance) the field. If increased sufficiently, corona (ionization of air molecules) may occur. For example, in the case of an electric field disturbed by a sharp pointed leaf tip.

2) For findings of specific laboratory studies on plant and animal cell cultures, the reader is referred to Reference [5] and [6] or some of the relevant Internet sites in Appendix B.

From the table above, it is clear that damage of leaf tips occur at fairly high electric field levels at locations very close to the line. Trees growing this close to the power line have to be pruned and trimmed according to the electric utility’s requirements for servitude management. At field levels outside the servitude, where tall trees are allowed and more likely to be found, the electric field levels will be low enough not to cause leaf tip damage.

Summary

Considering the findings of studies on the effects of electric and magnetic fields on plants, as noted in Table 8 above, it can be concluded that electric and magnetic fields with levels typical of a power line environment, complying with the requirements for proper servitude management as prescribed by the electric utility, are unlikely to affect plants in terms of growth, germination and crop production.

2.6 Exposure Limits

The guidelines for electric and magnetic field exposure set by the International Commission for Non-Ionising Radiation Protection (ICNIRP) [61], an organisation linked to the World Health Organisation (WHO), receive world-wide support [62] and are summarised in Table 9.

Table 9. Electric and magnetic field exposure guidelines set by ICNIRP (1998) [61].

	Electric Field (kV/m)	Magnetic Field (μT)
Reference Level		
Occupational	10	500
Public	5	100
	Current Density (mA/m^2)	
Basic Restriction:		
Occupational	10	
Public	2	

The ICNIRP guidelines are based on a Reference Level, a field level easily measured and spatially averaged across the volume taken up by the body of the exposed person, and a Basic Restriction. The Basic Restriction is presented, in this case, as a safe induced current density and is measured in milli-ampere per square metre (mA/m^2). Should the Reference Level be exceeded, then further evaluation is required to ensure that the Basic Restriction is not exceeded [65].

South Africa: Utilities, in South Africa, involved in the generation and distribution of electrical energy, are bound by the Occupational Health and Safety (OHS) Act [63] to provide such services in a safe manner. There are currently no regulations (under the Hazardous Substances Act) in terms of exposure to power frequency EMF in South Africa and the ICNIRP guidelines are used for assessing human exposure to these fields.

The exposure guidelines set by ICNIRP (1998) [61] are endorsed by the South African Department of Health as well as the South African Forum for Radiation Protection.

North America: No US federal recommendations exist currently for occupational or residential exposure to 60Hz magnetic fields [64]. The safety level set by the Institute for Electrical and Electronics Engineers (IEEE) include [66, 67]:

“The maximum permissible exposure level for the general public to electric fields is 5 kV/m, except on transmission line rights-of-way (servitude), where the limit is 10 kV/m”.

“The IEEE Standard explicitly increases the general-public Maximum Permissible Exposure (MPE) level for 60-Hz electric fields from 5 kV/m to 10 kV/m on transmission line rights-of-way. Exposure of the general public would not exceed the MPE of 10 kV/m, except in limited areas under some 765-kV lines”.

In some states, the maximum permitted fields are the maximum fields that existing lines produce at maximum load.

Europe: As far as limits for electric and magnetic field exposure applied in Europe are concerned, the European Standard: EN 50392 [68] is strongly based on the ICNIRP guidelines for exposure power frequency to electric and magnetic fields.

From the above, it is noted that utilities are typically guided by a maximum electric field limit of 10kV/m in the design of power lines, particularly 765kV lines. This maximum electric field limit (10kV/m) is based on safety considerations when a large vehicle (truck) parked underneath the line is touched by a well grounded (electrically earthed) person, for example. To meet this design limit, particularly for 765kV lines, the required minimum conductor clearance above ground is adjusted accordingly.

Safety of the public from electric and magnetic field exposure is ensured by application of the ICNIRP guidelines, typically at the servitude boundary as residence within the servitude is generally not allowed. Where exposure to electric and magnetic field levels above the ICNIRP guidelines may take place, special engineering techniques, as outlined in Section 2.7, can be applied to reduce the fields to more acceptable levels.

2.7 Can Fields be Reduced?

As noted earlier, shielding of the electric field can be achieved fairly easily by introducing conductive material into the field. For example, a wire mesh bonded to earth and supported by wooden poles covering the area that needs to be shielded. This technique is effective but may be considered as having significant visual impact. Depending on the desired field level, line compaction (bringing the conductors of the power line closer to each other) may also be applied. The effect of more compact tower designs (Delta configuration as opposed to Flat configuration) on partial field reduction has already been demonstrated in Figures 1 to 4. Field reduction by line compaction is limited because compaction in turn affects other electrical parameters, important to the safe and effective operation of the line.

Table 10. Summary of engineering techniques that can be applied to reduce power frequency magnetic fields from overhead power lines.

Technique	Brief Description	Field Reduction ⁽¹⁾	Cost ⁽¹⁾	Key Considerations
Line compaction	Reduction in phase spacing.	Marginal	Small	May introduce corona; May limit available techniques for live line maintenance.
Reverse phase	Reversal of phases on double circuit line: RWB – BWR	Good	Low	Only applicable to double circuit lines.
Delta	Conversion from horizontal flat configuration to delta configuration.	Good	Medium	May introduce corona.
Split phase	Splitting of phases to create additional phases with spatial placement to create significant field reduction.	Exceptional	High	Interphase spacers required; Increase in complexity of line structures; Limit available techniques for live line maintenance; Larger visual impact due to increase in conductors.
Shielding with loops	Conductive loop (passive and compensated) supported by additional poles.	Good	Low	Power dissipated by loop must be considered; Feasible only for local applications; Larger visual impact due to additional conductors.
Shielding with material	Use of high permeability material to shield a small area or product.	Exceptional	Low	Only small areas can be shielded at relatively low cost; Feasible only for local applications.
Underground cabling	Application of underground cabling as opposed to an overhead line.	Good	Very high	Maintenance more complex than lines;

Note: 1) Field reduction and cost are compared to a flat, horizontal configuration (See explanation below).

Although magnetic field reduction, to a certain extent, can be achieved by line compaction (See Figures 1 to 4), special engineering designs are required to reduce magnetic fields significantly. Table 10 summarises some of the methods, including specially engineered techniques, that can be applied to reduce magnetic fields if required.

With reference to Table 10, the following categories cover estimates of the cost of the field reduction technique [2]:

Low : Less than 10% of line cost;
Medium : 10 to 20% of line cost;
High : 20 to 50% of line cost;
Very high : More than 50% of line cost.

The following is indicative of the level of field reduction:

Marginal : Field reduction is less than a factor of 1,5;
Good : Field reduction is between 1,5 and 4;
Excellent : Field reduction is between 4 and 10;
Exceptional : Field reduction is greater than 10.

It should be noted that cost and electrical performance of the line strongly dictate the technique to be applied. Magnetic field mitigation is a highly technical subject and, in view of the scope of this report, is only briefly discussed. The reader requiring more technical detail about the techniques mentioned, is referred to References [2, 73, 74, 75]. The application of specific field reduction technique needs to be evaluated on a case by case basis.

2.8 International Opinion and Consensus

The following citations (in order of publication date: 2000 to 2004) summarise international opinion and consensus on the topic:

International Council on Large Electric Systems (CIGRE), 2000 [69].

Note: The opinion of CIGRE is included as CIGRE is viewed as an authority and source of technical information in the electric utility industry.

“As EMF science has improved and evolved, it has become increasingly clear that if exposure to EMF poses any health risk at all, the overall public health impact is small. Recent epidemiological studies, carried out on large populations, have not established a causal link between childhood or adult cancers and magnetic field exposure, although some weak and persistent statistical association remain unexplained. At the same time, laboratory studies on cells, tissues and whole animals have found no consistent or convincing evidence that power-frequency electric or magnetic fields in the workplace or at home produce harmful biological effects - nor has any credible mechanism been proposed by which such effects could occur.”

“The knowledge gained from this research is reassuring and in agreement with the actual position statement of the World Health Organization (WHO) and of the American National Institute of Environmental Health Sciences (NIEHS). It is CIGRE's view that there is no scientific justification for measures to reduce exposure to EMF through changes in the technology and management of existing high-voltage

power systems. Nevertheless, considering the existence of public concern and some scientific uncertainties, CIGRE will continue to monitor the issue and to update its view in the light of any new developments.”

World Health Organisation (WHO), 2001 [70].

“While the classification of ELF magnetic fields as possibly carcinogenic to humans has been made, it remains possible that there are other explanations for the observed association between exposure to ELF magnetic fields and childhood leukaemia. In particular, issues of selection bias in the epidemiological studies and exposure to other field types deserve to be rigorously examined and will likely require new studies. WHO therefore recommends a follow-up, focused research programme to provide more definitive information. Some of these studies are currently being undertaken and results are expected over the next few years.” (The EMF Project currently driven by the WHO is expected to be concluded in 2007).

US National Institute of Environmental Health Sciences (NIEHS) / National Institute of Health, 2002 [64, 71].

“Electricity is a beneficial part of our daily lives, but whenever electricity is generated, transmitted or used, electric and magnetic fields are created. Over the past 25 years, research has addressed the question of whether exposure to power frequency electric and magnetic fields (EMF) might adversely affect human health. For most health outcomes, there is no evidence that EMF exposures have adverse health effects. There is some evidence from epidemiological studies that exposure to power frequency magnetic field is associated with an increased risk of childhood leukemia. This association is difficult to interpret in the absence of reproducible laboratory evidence or a scientific explanation that links magnetic fields with childhood leukemia. EMF exposures are complex and come from multiple sources in the home and workplace in addition to power lines. Although scientists are debating whether EMF is a hazard to health, the NIEHS recommends continuing education on ways of reducing exposure”.

National Radiological Protection Board (NRPB) (UK), 2004 [72].

“Having considered the totality of the scientific evidence in the light of uncertainty and the need for a cautious approach, NRPB recommends that restrictions on exposure to EMF in the UK should be based on the guidelines issued by the International Commission on Non-Ionizing Radiation Protection (ICNIRP) in 1998.”

3. CONCLUDING REMARKS

The topic electric and magnetic fields from overhead power lines has been discussed in this report. In particular, a summary of technical and biological aspects based on a literature survey and field calculations is presented.

Overhead power lines generate electric and magnetic fields. Electric fields, measured in kV/m :

- Are linked to the voltage of the power line and remains relatively stable with the line energized.

- Can be reduced (shielded) fairly easily.
- Decrease with an increase in distance from the line.

Magnetic fields, measured in μT :

- Are linked to the current flowing (load) on the line. Magnetic field levels in the vicinity of a power line typically show daily and seasonal variation patterns.
- Can be reduced. Reducing magnetic fields require special engineering techniques or line designs.
- Decrease with an increase in distance from the line.

As household appliances and other electrical equipment also generate electric and magnetic fields (EMF), people are generally exposed to varying levels of EMF in their daily lives at work and at home.

Many (epidemiology, laboratory and live animal) studies have been conducted over the past three to four decades to determine whether health effects may arise from exposure to EMF. The main focus of the research has been on a possible association between long term exposure to magnetic fields and childhood leukemia. The suggestion for this health outcome stems mainly from some epidemiological studies.

This finding has not been confirmed by controlled laboratory studies: No evidence of a causal relationship between magnetic field exposure and childhood leukemia has been found and no dose-response relationship has been shown to exist between EMF exposure and biological effects.

A possible explanation for the epidemiological findings may be confounding or bias which render the data inconclusive and prevent resolution of the inconsistencies in the epidemiologic data.

Because of the lack of a known biophysical mechanism that would explain these effects, many question the existence of *clinical* responses. *Clinical* responses, if any, as a result of power frequency electric and magnetic field exposure to levels typically found in residential and power line environments, if any, appear insignificant.

The absence of evidence on health effects is generally not considered to mean evidence of the absence of health impacts and has resulted in some scientists advocating caution (precautionary principle) and finding ways to avoid or reduce exposure.

Studies on the behaviour, reproduction, health, meat production, milk production and navigation have found minimal or no effects of EMF on animals.

Past studies have found no significant effect of EMF on plant growth, crop production and seed germination. No recent studies of plants growing near transmission lines have been conducted.

The guidelines for electric and magnetic field exposure set by the International Commission for Non-Ionising Radiation Protection (ICNIRP) receives world-wide support and are endorsed by the Department of Health in South Africa.

Calculations of electric and magnetic field levels created by overhead power lines have shown that areas where members of the public may be exposed (at the servitude boundary and further away from the line) are well within the ICNIRP guidelines. Where necessary and where field levels exceed the ICNIRP guidelines within the servitude, techniques exist to reduce the field levels.

4. APPENDIX A – LINE GEOMETRY

The following tower geometries were used in calculating the field profiles indicated in Figures 1 to 6.

765kV Lines

765kV - Flat Configuration

Descriptor	Value / Name	Unit
Servitude width	80	m
Conductor bundle type	Tern	
Bundle diameter	64	cm
No of sub-conductors per bundle	6	
Sub-conductor diameter	27	mm
Phase spacing	15,8	m
Phase A – height above ground	17	m
Phase B – height above ground	17	m
Phase C – height above ground	17	m
Sub-conductor spacing	320	mm

765kV - Compact Cross-rope

Descriptor	Value / Name	Unit
Servitude width	80	m
Conductor bundle type	Tern	
Bundle diameter	64	cm
No of sub-conductors per bundle	6	
Sub-conductor diameter	27	mm
Phase spacing	14	m
Phase A – height above ground	20	m
Phase B – height above ground	17	m
Phase C – height above ground	20	m
Sub-conductor spacing	320	mm

765kV - Delta

Descriptor	Value / Name	Unit
Servitude width	80	m
Conductor bundle type	Tern	
Bundle diameter	64	cm
No of sub-conductors per bundle	6	
Sub-conductor diameter	27	mm
Phase spacing	7	m
Phase A – height above ground	29	m
Phase B – height above ground	17	m
Phase C – height above ground	29	m
Sub-conductor spacing	320	mm

400kV Lines

400kV - Flat Configuration

Descriptor	Value / Name	Unit
Servitude width	47	m
Conductor bundle type	Tern	
Bundle radius	32,9	cm
No of sub-conductors per bundle	3	
Sub-conductor diameter	27	mm
Phase spacing	8,5	m
Phase A – height above ground	13,1	m
Phase B – height above ground	13,1	m
Phase C – height above ground	13,1	m
Sub-conductor spacing	570	mm

400kV - Compact Cross-rope

Descriptor	Value / Name	Unit
Servitude width	47	m
Conductor bundle type	Tern	
Bundle radius	32,9	cm
No of sub-conductors per bundle	3	
Sub-conductor diameter	27	mm
Phase spacing	8,2	m
Phase A – height above ground	14,3	m
Phase B – height above ground	13,1	m
Phase C – height above ground	14,3	m
Sub-conductor spacing	570	mm

400kV - Delta

Descriptor	Value / Name	Unit
Servitude width	47	m
Conductor bundle type	Tern	
Bundle radius	32,9	cm
No of sub-conductors per bundle	3	
Sub-conductor diameter	27	mm
Phase spacing	3,5	m
Phase A – height above ground	19,3	m
Phase B – height above ground	13,1	m
Phase C – height above ground	19,3	m
Sub-conductor spacing	570	mm
